

The Photocyclisation of 1,2-Diarylpyridinium Cations and the Photobiscyclisation of 1,2,6-Triarylpyridinium Cations¹

By Alan R. Katritzky,* and Zuriati Zakaria, School of Chemical Sciences, University of East Anglia, Norwich NR4 7TJ

Edward Lunt, Pharmaceutical Chemistry Department, Pharmaceutical Division, May and Baker Ltd., Dagenham, RM10 7XS

Photocyclisation of 1-(2-pyridyl)-2-arylpyridiniums yields benzo[*c*]pyrido[1,2-*a*]-1,8-naphthyridinylium cations. Photobiscyclisation of 1,2,6-triarylpyridiniums gives benzo[8,9]quinolizino[4,5,6,7-*fed*]phenanthridinylium cations and their 9-*aza*-derivatives. Electron donor substituents tend to lower the yields which are otherwise high. The structures are supported by X-ray crystallographic analysis and by ultraviolet and n.m.r. spectra.

In the course of investigations in connection with polyarylpiperidines as leaving groups,² our attention was attracted to the polyarylpiperidinium betaines of type (1)

as a potential source of benzyne *via* a photochemical decarboxylative elimination analogous to that observed with benzenediazonium-2-carboxylate.³ Photolysis of this betaine led, however, not to benzyne, but to a

photoelectrocyclisation. This result led us to a more thorough investigation of the photochemistry of polyarylpiperidinium betaines and related pyridinium salts, some of the results of which are reported in this paper.

Photochemical cyclisations of polyphenyls to condensed benzenoid derivatives are well-documented,⁴ and the configurational restraints in the model stilbene system, (3)→(4), have recently been reported.⁵ In the heterocyclic field, similar cyclisations have been found in xanthylium and acridinium salts⁶ and later for pyridone analogues of stilbene.⁷ Recently, Dorofeenko and his co-workers⁸ reported the photocyclisation of 1,2-diphenylpyridinium salts, *e.g.* (5a), to fused tetracyclic derivatives (6a). In the course of our investigation we have independently confirmed the cyclisation (5a)→(6a), but under our conditions⁹ the 1,2,6-triphenyl derivative (5c) underwent a double cyclisation to give the fused hexacycle (7a), a derivative of the previously unknown benzo[8,9]quinolizino[4,5,6,7-*fed*]phenanthridinylium ring system.† The present paper is concerned with the extension of this reaction to other polyarylpiperidinium salts and betaines of this type, as well as a brief consideration of the mechanism of the photocyclisation and the factors affecting the outcome of the reaction.

RESULTS AND DISCUSSION

Preparation of Pyridinium Salts and Betaines.—The pyridinium salts (Tables 1, 2) were in general prepared using standard procedures by reaction of the corresponding polyarylpiperidinium salts with anilines or amino-heterocycles. Use of carboxy-substituted anilines, followed by treatment of the product with base led to the appropriate betaines (Table 3), as shown by the disappearance of carbonyl and perchlorate bands in the i.r. spectrum at 1720 and 1080 cm⁻¹ respectively. Most of the betaines (and many of the polycyclic photo-reaction products) crystallise with small variable amounts of water of crystallisation; this is difficult to remove and is not readily amenable to accurate determination using, *e.g.*, the Karl-Fischer reagent, but shows in the i.r. spectrum. Low yields were obtained in some pyridin-

† In unpublished work with Dr. El-Shafie we have shown that under different conditions the intermediate product (6c) of monocyclisation can be isolated.

ium salt preparations in EtOH due to a side-reaction involving hydrolysis to pyrylium salt pseudo-base, and in these cases the use¹⁰ of anhydrous HCONMe₂ as solvent for the reaction may be preferable. The physical properties of pyridinium salts and betaines prepared in this manner are given in Table 3. The pyridinium

methanol at 300 nm has led to the same product in similar yield. However, the corresponding 1-(*o*-substituted phenyl)-2-methylbetaine (1c) failed to cyclise: for this compound models indicate considerable steric interaction in the transition state as well as in the product (see below).

Presumably the reaction occurs in two stages *via* the intermediate monocyclised product (6c) (but we have been unable to isolate any of this material). The use of various methyl-substituted tetra-arylpiperidinium salts

gave the corresponding substituted phenanthridinium salts in low to fair yields as indicated in Table 4.

It has not proved possible to detect presumed dihydro-

(8)

intermediates such as (8), but the occurrence of colour changes on admission of air to the reaction vessel, coupled with the increased yields obtained when the

reaction was carried out in oxygen, argues in favour of such expected intermediates (see below). The existence

^a In (CD₃)₂SO. ^b Spectrum shows the presence of (12e) as a minor component δ 9.5 (d, *J* 2 Hz, 9-H), 8.7 (s, 13-H), and 2.65 (s, Me).

reaction for a series of substituted compounds shows clearly that electron-donating substituents (but not electron-withdrawing) disfavour the reaction. For example, the yield of product decreases progressively (Table 4) on the successive introduction of methyl substituents into the 1-, 2-, 4-, and 6-aryl rings, whilst with *o*- or *p*-hydroxy or *o*-methyl substituents in the 1-aryl ring, no product was obtained (although the *o*-methyl group may also exert a strong steric effect, see above).

On the other hand, where the possibility exists [in betaine (1b)] of alternative cyclisations to a phenyl or a *p*-tolyl group, the latter seems to be preferred judged by the ratio of major to minor product (see Experimental section), but this may reflect other (steric) factors as in the corresponding 1-(2-pyridyl) salt (11d) the situation is reversed.

The reaction with the 1,2,4,6-tetraphenylpyridinium salts is a high yield one for photochemical reaction reflecting the extreme ease, as can be clearly seen from models, of the $4n + 2$ anti-Hückel conrotatory process leading to the presumed *trans*-dihydro-intermediate (8). [The possibility of a thermally allowed 1,3-prototropic shift to the more stable dihydro-derivative (13) prior to oxidative aromatisation cannot be discounted (*cf.* ref. 12).] Photocyclisations of this type have been shown¹³ to proceed through π - π^* lowest excited singlet states, and the effect of steric restriction of the conrotative process in this state by the attachment of a 2',3'-ethano-bridge in the starting pyridinium salt is well illustrated by the low cyclisation yield obtained with (14).

Substitution of the 1-aryl group with electron-withdrawing substituents as in the 4-pyridyl derivatives

pyridine substitution also seemed to cause a marked decrease in yield.

Spectra of Monocyclisation Products.—(a) ¹H N.m.r. spectra. The ¹H n.m.r. spectra of the various benzo[*c*]-pyrido[1,2-*a*][1,8]naphthyridinium salts and betaines

prepared in this work are shown in Table 5. Apart from the general movement to lower field of aromatic protons compared to their position in the spectra of the parent triaryl pyridinium derivatives expected from the increased ring current in the new 14π -annular system, a principal feature of the spectra is the occurrence of two groups of multiple aromatic proton resonances cor-

TABLE 6

and the carboxy-betaines is clearly not deleterious. In the 1-(4-pyridyl) series of compounds, the adverse effects of increasing methyl substitution are once more observed. The 1-(2-pyridyl) derivatives, however, in general gave relatively low yields. These general observations are broadly in line with those substituent effects observed by previous workers¹⁴ in the related photocyclisation of stilbenes to phenanthrene derivatives, in which case,

responding to the angular (bay or α -) protons and non-angular (peninsular or β -) protons characteristic for the isosteric triphenylenes.¹⁵ For example, in (2a) these occur at δ 8.8 and 8.0 respectively. Also clearly visible at low field are the 7,9-proton resonances as doublets or in (2a) as a coincidental singlet.

The support for the proposed structures is most clearly demonstrated in the series of 4-aza-derivatives

(10a—c), where the substitution effected considerable simplification. For example in (10c) 1-H appears at low field as a doublet of doublets at δ 9.2, coupled to 2-H (δ 8.1, m) and 3-H, a quartet at δ 7.7. 7-H and 9-H form an AB quartet at δ 8.5, 9.5 whilst 10-H, 13-H (angular) are seen as doublets of doublets at δ 9.35, 8.85 and 1-H, 12-H (non-angular) as a combined multiplet at δ 8.1 as expected.

(b) *Ultraviolet spectra* (Table 6). The hexacyclic

has been carried out (Figure) and is in complete agreement with the proposed structure (7a). Particularly prominent at low field are the resonances for C-23 and C-1,5 showing the effect of the adjacent charged nitrogen centre.

(b) *U.v. spectra* (Table 8). These compounds show a very characteristic pattern of nine bands (A—I) near 223, 243, 278, 303, 323, 349, 365, 411, and 433 nm. Mean and standard deviations (Table 6) show that the

Expanded ^{13}C n.m.r. spectrum in $(\text{CD}_3)_2\text{SO}$ of 2-phenylbenzo[8,9]quinolizino[4,5,6,7-fed]phenanthridinium perchlorate (7a)

derivatives display characteristic ultraviolet spectra: a system of seven bands (A—G) of which the wavelengths and extinction coefficients are relatively constant (see Table 6 for means and s.d.): they occur at average values of 213, 249, 278, 301, 330, 363, and 402 nm.

Spectra of 2-Arylbenzo[8,9]quinolizino[4,5,6,7-fed]phenanthridinium Salts and Betaines.—(a) ^1H N.m.r. spectra (Table 7). The most notable effect on the proton spectrum of the double cyclisation is the considerable simplification due to the symmetry (or near symmetry). The 1,3-protons now appear as 2 H singlets at low field, whilst the groups of angular (4, 14-H, 9-H, 7, 11-H) and higher field non-angular (5, 13-H, 6, 12-H) are clearly distinguished. For example, in the 9-aza-trimethyl derivative (7d) where the substitutions affect further simplification, the 1,3-H singlet is at δ 9.0. The angular 4,14-H; 7,11-H show as doublet and broad singlet respectively at δ 8.75, 8.4, the non-angular 5,13-H as a broad doublet at δ 7.45, and the aza-ring protons 8,10-H as an extreme low field singlet at δ 9.8.*

(b) ^{13}C N.m.r. spectra. The proton decoupled ^{13}C n.m.r. spectrum of compound (7a) showed 16 of the theoretically expected 17 lines. A complete assignment

effects of substitution on this pattern of frequencies and on the intensities is minor.

EXPERIMENTAL

Melting points were determined with a Reichert apparatus and are uncorrected. Spectra were recorded with the following instruments: i.r., Perkin-Elmer 257; mass, Hitachi-Perkin-Elmer RMU-6E; u.v., Unicam SP800A; n.m.r., R12 Perkin-Elmer and Varian HA-100 and ^{13}C n.m.r., FX 100 JEOL. In all n.m.r. measurements, tetramethylsilane was used as an internal standard. Irradiations with an external source were performed with a Rayonet reactor (RPQ-100), with 3 500 Å, 3 000 Å, or 2 537 Å lamps in quartz flasks.

Preparation of 2,4,6-Trisubstituted Pyrylium Salts.—2,4,6-Triphenylpyrylium perchlorate (16b),¹⁶ m.p. 280 °C, 2-methyl-4,6-diphenylpyrylium perchlorate (16a),¹⁷ m.p. 274 °C, 2,4-diphenyl-6-*p*-tolylpyrylium perchlorate (16c),¹⁸ m.p. 225 °C, 2,6-diphenyl-4-*p*-tolylpyrylium perchlorate (16d),¹⁸ m.p. 279 °C, and 5,6-dihydro-2,4-diphenylnaphtho[1,2-*b*]pyrylium tetrafluoroborate (17),^{19,†} m.p. 270–273 °C were prepared by previously described methods.

*2,4,6-Tri-*p*-tolylpyrylium Perchlorate* (16e).—4,4'-Dimethylchalcone²⁰ (69.15 g, 0.2 mol) and 4-methylacetophenone (21.75 g, 0.16 mol), were heated together at 100 °C for 2 h. The mixture was treated with perchloric acid (73% aq.; 30.25 g, 0.22 mol), stirred vigorously for 2 h, EtOH

* The ^1H and ^{13}C n.m.r. spectra of (7a) are significantly altered by the presence of traces of water; some of the present assignments may need modification (unpublished work with Miss B. J. Agha).

† We thank Miss A. Chermprapai for the sample.

(50 ml) was added and the whole heated under reflux for 0.5 h. The solid was separated by filtration, the solution was diluted with Et₂O (360 ml), and the precipitated orange solid collected. Recrystallisation of the combined solid product from MeOH–Et₂O (1 : 5) gave the *perchlorate* (16e)

(see Table 1). The precipitated solid was filtered off after cooling, and if necessary addition of ether, and recrystallised from a suitable solvent as indicated. The yields and physical properties of pyridinium salts prepared in this manner are given in Table 1 and the analytical data for

as orange microprisms (21.45 g, 30%), m.p. 310 °C (decomp.) (Found: C, 69.3; H, 5.4. C₂₈H₂₃ClO₄ requires C, 69.3; H, 5.1%); ν_{max} (Nujol) 1 630 (C=C) and 1 085 (ClO₄) cm⁻¹; δ(CF₃CO₂H) 2.55 (9 H, s), 7.85 (12 H, m), and 8.36 (2 H, s).

Preparation of Pyridinium Salts from 2,4,6-Trisubstituted Pyrrolium Salts.—General procedure. A mixture of the appropriate pyrrolium salt and amine in absolute EtOH was heated under reflux for 3 h, or, in the case of the carboxy-substituted salts, until the reaction was complete

these and their photocyclisation products are given in Table 2.

Preparation of Betaines from Carboxy-substituted Pyridinium Salts.—2-(2,4,6-Triphenyl-1-pyridinio)benzoate (1a). To a solution of 1-(2-carboxyphenyl)-2,4,6-triphenylpyridinium perchlorate (1f) (1 g, 0.001 9 mol) in the minimum of MeOH (25 ml) was added solid KOH (0.2 g, 0.003 mol) until pH 8–9. The reaction mixture was stirred for 25 min and the precipitated potassium perchlorate filtered off. The MeOH filtrate was concentrated to 10 ml in

concentrated *in vacuo* to give a second crop, and the combined solids recrystallised from a suitable solvent.

2-Methyl-1,4,6-triphenylpyridinium Perchlorate.—The salt (0.5 g) in MeOH (150 ml) was photolysed at 300 nm for 24 h as described above. The solid obtained was recrystallised from MeCN–MeOH to give 6-methyl-8-phenylbenzo[*c*]pyrido[1,2-*a*][1,8]naphthyridinium perchlorate (6a) as yellow needles (0.08 g, 16%), m.p. 244 °C (decomp.) [lit.,²² m.p. 212 °C (decomp.)] (Found: C, 68.3; H, 4.6; N, 3.2. Calc. for C₂₄H₁₈ClNO₄: C, 68.7; H, 4.3; N, 3.3%); ν_{max} (CHBr₃) 1 620s, 1 600s, 1 590m, 1 530m, 1 485w, 1 455s, 1 440s, 1 410m, 1 380m, 1 345w, 1 270m, 1 210w, 1 080brs, 875m, and 750s cm⁻¹.

1,2,4,6-Tetraphenylpyridinium Perchlorate.—The salt (0.5 g) in MeOH (300 ml) was photolysed at 300 nm for 24 h as described above. The solid product was recrystallised from MeOH as yellow needles to give 2-phenylbenzo[8,9]-quinolizino[4,5,6,7-*fed*]phenanthridinium perchlorate (7a) (0.42 g, 85%), m.p. 340 °C (decomp.) (Found: C, 72.2; H, 3.7; N, 2.9. C₂₉H₁₈ClNO₄ requires C, 72.5; H, 3.8; N, 2.9%); ν_{max} (Nujol) 1 625s, 1 600m, 1 525m, 1 485m, 1 445m, 1 410m, 1 340m, 1 295m, 1 080br, 855w, 745s, and 680s cm⁻¹. Similar photocyclisation (300 nm, 24 h) of the corresponding pyridinium chloride (0.5 g) gave the corresponding *chloride* (0.46 g, 93.5%), m.p. 340 °C (decomp.) (Found: C, 81.6; H, 4.5; Cl, 8.3; N, 3.4. C₂₉H₁₈ClN·0.5H₂O requires C, 82.0; H, 4.5; Cl, 8.4; N, 3.3%).

The i.r. spectrum was very similar to that of the perchlorate salt above.

Details of other benzo[*c*]pyrido[1,2-*a*][1,8]naphthyridinium and benzo[8,9]quinolizino[4,5,6,7-*fed*]phenanthridinium salts and betaines prepared by analogous photocyclisations are given in Table 4.

We thank the National University of Malaysia for financial assistance (to Z. Z.), also Mr. D. S. Potter and Dr. M. Podmore (May and Baker Ltd.) for assistance with some microanalyses and n.m.r. spectra respectively.
